Amendments to the Claims

1. (Previously Presented) A cable network, comprising:

a cable modem (CM) for transmitting and receiving data;

a media access control frame structure in the cable network to initialize payload header

suppression of transmitted data packets through extended header types, the media access control

frame comprising:

a media access control header including various extended header types according to a

service flow of data packets between a sender and a receiver over the cable network to be

inserted in a payload data unit to initialize a payload header suppression rule; and

a payload data unit comprising payload header suppression parameters other than those

defined in the various extended header types according to a payload header suppression rule to

permit initialization of payload header suppression using the defined PHS rule parameters in the

various extended header types and the payload header suppression parameters in the payload data

unit other than those defined in the various extended header types.

2. (Previously Presented) The cable network of claim 1, wherein the media access

control header comprises:

a frame controller for controlling a frame;

a MAC PARM part that is a media access control parameter and shows the number of

minislots or asynchronous transfer mode cells;

a LEN part for showing the length of the media access control frame;

Art Unit 2616

an EHDR part for showing the type, the length, the value, and the payload header

suppression index of an extended header and changing the payload header suppression rule using

3 extended types; and

a header check sequence for checking the media access control header.

3. (Previously Presented) The cable network of claim 1, wherein the media access

control header comprises an EHDR part for showing the type, the length, the value, and the

payload header suppression index of the extended header and changing the payload header

suppression rule using the 3 extended types.

4. (Previously Presented) The cable network of claim 1, wherein the payload data

unit comprises:

a source address part for showing the address of the sender for transmitting suppressed

payload header information;

a destination address part for showing the address of the receiver, to which the

suppressed payload header information is to be received;

a type/length part for showing the type and the length of the suppressed payload header

information;

user data having information data and parameters according to the payload header

suppression rule; and

a cycling redundancy checking unit for checking the error of media access control frame

data.

5. (Previously Presented) The cable network of claim 4, wherein the parameters

according to the payload header suppression rule comprise a payload header suppression size, a

payload header suppression field, a payload header suppression mask, and a payload header

suppression verification.

6. (Previously Presented) A data communication method in a cable network,

comprising the steps of:

transmitting a first EH_TYPE data packet according to its payload header suppression

rule to a receiver when the payload header suppression rule differs from the payload transmission

rule of a preceding data transmission packet, in the case where communication is performed

between a sender and the receiver;

checking whether there exists an error in the first EH TYPE data packet that has been

transmitted to the receiver, determining whether to apply a new payload header suppression rule

on the basis of the first EH TYPE, and transmitting a second EH TYPE data packet to the

sender; and

terminating transmission to the receiver of a common payload header suppression

packet, setting a packet type as a third EH TYPE, suppressing a packet into a new channel, and

transmitting the packet when the second EH TYPE packet is a success message and setting the

packet type as a common media access control packet and transmitting the packet without

performing suppression when the second EH_TYPE packet is a failure message.

7. (Original) The data communication method of claim 6, wherein the second

EH TYPE packet comprises a success or failure message.

8. (Original) The data communication method of claim 6, wherein the sender

continuously transmits the first EH TYPE to the receiver until the second EH TYPE packet is

received from the receiver.

9. (Original) The data communication method of claim 6, further comprising a step

of the sender determining that the receiver cannot support a new payload header suppression rule.

10. (Previously Presented) A data communication method in a cable network,

comprising the steps of:

transmitting a first EH TYPE packet according to change in a payload header

suppression rule to a receiver when the payload header suppression rule changes, in the case

where communication is performed between a sender and the receiver;

checking whether there exists an error in the first EH TYPE packet, determining

whether to apply a new payload header suppression rule on the basis of the first EH TYPE, and

transmitting a second EH TYPE data packet to the sender; and

terminating transmission to the receiver of a common payload header suppression

packet, setting a packet type as a third EH_TYPE, suppressing a packet into a new channel, and

transmitting the packet when the second EH_TYPE packet is a success message and setting the

packet type as a common media access control packet and transmitting the packet without

performing suppression when the second EH TYPE packet is a failure message;

wherein the first EH_TYPE packet is set as a packet whose EH_TYPE is 7, the second

EH_TYPE packet is set as a packet whose EH_TYPE is 8, and the third EH_TYPE packet is set

as a packet whose EH_TYPE is 6 when the sender transmits the data to the receiver and wherein

the first EH_TYPE packet is set as the packet whose EH TYPE is 7, the second EH TYPE

packet is set as the packet whose EH_TYPE is 8, and the third EH TYPE packet is set as the

packet whose EH TYPE is 5 when the receiver transmits the data to the sender.

11. (Currently Amended) A data communication method_usable_in a cable network

comprising a cable modem (CM) for transmitting and receiving data, a media access control

frame structure in the cable network to initialize payload header suppression of transmitted data

packets through extended header types, the media access control frame comprising a media

access control header including various extended header types according to a service flow of data

packets between a sender and a receiver over the cable network to be inserted in a payload data

unit to initialize a payload header suppression rule; and a payload data unit comprising payload

header suppression parameters other than those defined in the various extended header types

according to a payload header suppression rule to permit initialization of payload header

suppression using the defined PHS rule parameters in the various extended header types and the

payload header suppression parameters in the payload data unit other than those defined in the

various extended header types, the method comprising the steps of:

transmitting a first EH_TYPE data packet according its payload header suppression rule

to a receiver when the payload header suppression rule differs from the payload transmission rule

of a preceding data transmission packet, in the case where communication is performed between

a sender and the receiver; and

checking whether there exists an error in the first EH_TYPE data packet that has been

transmitted to the receiver, determining whether to apply a new payload header suppression rule.

and transmitting a second EH TYPE packet to the sender.

12. (Original) The data communication method of claim 11, wherein the sender

continuously transmits the first EH TYPE packet to the receiver until the second EH TYPE

packet is received from the receiver.

13. (Original) The data communication method of claim 11, further comprising a step

of determining that the receiver cannot support the new payload header suppression rule when

the second EH_TYPE packet is not received from the receiver for a predetermined time.

14. (Currently Amended) A data communication method in a cable network,

comprising:

transmitting a first EH_TYPE packet according to change in a payload header

suppression rule to a receiver when the payload header suppression rule changes, in the case

where communication is performed between a sender and the receiver; and

checking whether there exists an error in the first EH TYPE packet, determining

whether to apply a new payload header suppression rule, and transmitting a second EH_TYPE

packet to the sender;

wherein the first EH TYPE packet transmitted and received by the sender and the

receiver is set as the a packet whose EH TYPE is 7, the a second EH TYPE packet is set as the a

packet whose EH_TYPE is 8, and the_a third EH_TYPE packet is set as the_a packet whose

EH_TYPE is 6 when the sender transmits the data to the receiver and wherein the first

EH_TYPE packet is set as the packet whose EH TYPE is 7, the a second EH TYPE packet is

set as the a packet whose EH TYPE is 8, and the a third EH TYPE packet is set as the a packet

whose EH TYPE is 5 when the receiver transmits the data to the sender.

15. (Original) The data communication method of claim 11, further comprising a step

of terminating the transmission of the common payload header suppression packet, setting the

packet type as the third EH TYPE, suppressing the packet into the new channel, and transmitting

the packet when the second EH TYPE packet is the success message.

16. (Original) The data communication method of claim 11, further comprising a step

of setting the packet type as the common media access control packet and transmitting the packet

without performing the suppression when the second EH TYPE packet is the failure message.

17. (Currently Amended) A method of using a media access control frame structure in a cable network comprising a cable modem (CM) for transmitting and receiving data, a media access control frame structure in the cable network to initialize payload header suppression of transmitted data packets through extended header types, the media access control frame comprising a media access control header including various extended header types according to a service flow of data packets between a sender and a receiver over the cable network to be inserted in a payload data unit to initialize a payload header suppression rule; and a payload data unit comprising payload header suppression parameters other than those defined in the various extended header types according to a payload header suppression rule to permit initialization of payload header suppression using the defined PHS rule parameters in the various extended header types and the payload header suppression parameters in the payload data unit other than those defined in the various extended header types to initialize payload header suppression of

defining payload header suppression rule parameters in various extended header types in a media access control header according to a service flow of data packets between a sender and a receiver to be inserted in a payload data unit to initialize a payload header suppression rule; and

transmitted data packets through extended header types, the method comprising:

inserting into a payload data unit payload header suppression parameters other than those defined in the various extended header types according to a payload header suppression rule to initialize payload header suppression using the defined PHS rule parameters in the various extended header types and the payload header suppression parameters in the payload data unit other than those defined in the various extended header types.
